JaguarPC is a Cross-Platform Web-Application Development environment created by JaguarPC.com. JaguarPC provides a set of tools to help you design, create, and deploy Rich Internet Application. JaguarPC is capable of developing Web applications using a variety of technologies including Apache Flex, Adobe Flex, Adobe Flash (ActionScript), Microsoft Silverlight, Microsoft XNA Game Studio, and web-application frameworks like ASP.NET or Java servlets. JaguarPC is developed and supported by JaguarPC.com. For more information please visit our website at [www.jaguarpc.com](http://www.jaguarpc.com). Features:

- Powerful C++ Web Application Builder JaguarPC Web Application Builder is a fast, intuitive, and easy-to-use Rapid Application Development environment for Microsoft.NET Framework, J2EE, and C++ technologies. This C++ development environment can be used for creating web applications using these technologies. The building process is very fast and easy and requires no programming skills or development experience. The environment comes with a sample application that you can use as a guideline to understand the process of application development.
- Rich Internet Application Development Environment A first-of-its-kind toolset for creating rich Internet applications and web services, JaguarPC provides an integrated development environment for Windows and Linux. The environment contains the powerful components required for the design, creation, and deployment of Rich Internet Applications.
- HTML5 Compatible The environment can be developed and deployed in any HTML5-compliant browsers.
- Cross-Platform The builder creates HTML5 documents in the W3C standard and can be deployed in any HTML5-compliant browsers for any platform.

Requirements:

- .NET Framework 4.0 or above The W3C standard or the W3C standard for web applications has been adopted by Microsoft, Apple, Mozilla, and web browser makers. It is the most recent web application standard that supports HTML5 and CSS3 content. Web applications can be written in other technologies as well, such as Adobe Flex or Microsoft Silverlight.

.NET Framework .NET Framework is a cross-platform, object-oriented development platform that enables you to write, debug, and deploy applications on different platforms that target multiple operating systems, including Windows, Windows Mobile, and Windows CE. The .NET Framework is based on Microsoft's Common Language Runtime and is targeted at a variety of programming languages:

Advantages: Reliable Disadvantages: Reliably checks URL's as well as check IP addresses via Ping. Some URLs may not work properly (Google's site is not working right now for example), so it's best to check the status of only URLs that do work properly. Gets the details of the page you view - e.g. the page title, whois, the latitude and longitude, the name of the domain, etc. In order to check the status of a website via a URL, first we have to write a script that will look for and process a response with the HTTP server you want to check. This is the response we will read to determine whether the given URL is OK or not, and then update a widget with the result. If you're running a dynamic website that uses a bunch of "hidden" pages that you're checking constantly, then you're pretty much wasting time whenever you need to generate the javascript to do these checks because you're running a script that will generate code that only becomes valid when you get the true "status" of the page. Of course, there's still a chance that the status of the hidden page will change before you can generate the javascript to display it. Here's a simple script that will do the job for us. It basically has a loop that is continuously running that checks every 10 seconds or so to see if a page or some URL is still OK. When you look at this, if it says `no_current_results`, it means the url hasn't changed since it was last checked. If it says something else, it means the url changed. (In the 'url' variable, you can just enter the url you want to check into the script. The widget will pick it up and display the result. You can place this url in your browser and it will automatically check the status as if you were doing this in your own browser.) -Take a look at a couple of websites to see if any of them work. Check that the url gives you a "page not found" or "redirects" message. This is a crucial step because you will be retrieving the text of the actual page that is being served up by the site. Simply browse through a website and see if you see the redirection message ("page not found") or the 09e8f5149f

Minimum: OS: Windows XP SP2 or Windows Vista SP1 or Windows 7 Processor: Intel Core 2 Duo, 2GHz Memory: 2GB RAM Graphics: Microsoft DirectX 9 or OpenGL 1.3 capable Sound: DirectX 9.0c compatible sound card Network: Broadband Internet access Recommended: Processor: Intel Core i5, 2.5GHz Memory: 4GB RAM Graphics: Microsoft DirectX
